Lecture 13: Spatial Models (Cont.)

Big Data and Machine Learning for Applied Economics Econ 4676

Ignacio Sarmiento-Barbieri

Universidad de los Andes

September 21, 2021

Recap

- Closeness
- ► Weights matrix
- Examples of weight matrices weights matrices in R
- Example of spatial regression.

Agenda

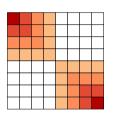

- 1 Motivation
- 2 Spatial Lag Model
 - Maximum Likelihood Estimator
 - Two-Stage Least Squares estimators
- 3 Interpretation of Parameters
- 4 Further Readings

Motivation

"Everything is related to everything else, but close things are more related than things that are far apart" (Tobler, 1979).

$$y = X\beta + u$$

- Independence assumption between observation is no longer valid.
- ► Attributes of observation *i* may influence the attributes of observation *j*.
- Spatial dependence introduces a misspecification problem.

Motivation

"Everything is related to everything else, but close things are more related than things that are far apart" (Tobler, 1979).

- One of the major differences between standard econometrics and standard spatial econometrics lies, in the fact that, in order to treat spatial data, we need to use two different sets of information.
 - 1 Observed values of the economic variables.
 - 2 Particular location where those variables are observed and to the various links of proximity between all spatial observations.

Spatial Econometrics: Weights Matrix

▶ At the heart of traditional spatial econometrics is the definition of the *weights matrix*:

$$W = \begin{pmatrix} w_{11} & \dots & \dots & w_{n1} \\ \vdots & w_{ij} & & \vdots \\ \vdots & & \ddots & \vdots \\ w_{n_1} & \dots & \dots & w_{nn} \end{pmatrix}_{n \times n}$$
(1)

- with generic element: $w_{ij} = \begin{cases} 1 & \text{if } j \in N(i) \\ 0 & \text{o.w} \end{cases}$
- ▶ N(i) being the set of neighbors of location j. By convention, the diagonal elements are set to zero, i.e. $w_{ii} = 0$.
- lacksquare Quite often the W matrices are standardized to sum to one in each row $w_{ij}^*=rac{w_{ij}}{\sum_{j=1}^n w_{ij}}$

Spatial Autoregressive (SAR) Models

Let's consider the following model:

$$y = \lambda Wy + X\beta + u$$

we assume that *W* is exogenous

If *W* is row standardized:

- ► Guarantees $|\lambda|$ < 1 (Anselin, 1982)
- ▶ [0,1] Weights
- ► *Wy* Average of neighboring values
- ▶ W is no longer symmetric $\sum_i w_{ij} \neq \sum_i w_{ji}$ (complicates computation)

Maximum Likelihood Estimator

Note that we can write

$$(I - \lambda W)y = X\beta + u$$

- ▶ We can think this model as a way to correct for loss of information coming from spatial dependence.
- $(1 \lambda W)y$ is a spatially filtered dependent variable, i.e., the effect of spatial autocorrelation taken out

In this case, endogeneity emerges because the spatially lagged value of y is correlated with the stochastic disturbance.

$$E((Wy)u') \neq 0 \tag{2}$$

Proof.

Note that
$$y = (I - \lambda W)^{-1} X \beta + (I - \lambda W)^{-1} u$$

Then

$$E((Wy)u') = E(W(I - \lambda W)^{-1}X\beta u' + W(I - \lambda W)^{-1}uu')$$
(3)

$$= W(I - \lambda W)^{-1} X \beta E(u') + W(I - \lambda W)^{-1} E(uu')$$

$$=W(I-\lambda W)^{-1}E(uu') \tag{5}$$

$$= \sigma^2 W (I - \lambda W)^{-1} \neq 0 \tag{6}$$

(4)

Maximum Likelihood Estimator

- ▶ One solution that emerged in the literature is MLE.
- ▶ We need an extra assumption, i.e., $u \sim_{iid} N(0, \sigma^2 I)$.

$$y = (I - \lambda W)^{-1} X \beta + (I - \lambda W)^{-1} u$$

note that

$$E(y) = (I - \lambda W)^{-1} X \beta + (I - \lambda W)^{-1} u$$
$$= (I - \lambda W)^{-1} X \beta + (I - \lambda W)^{-1} E(u)$$
$$= (I - \lambda W)^{-1} X \beta$$

Maximum Likelihood Estimator

$$E(yy') = ((I - \lambda W)^{-1}X\beta + (I - \lambda W)^{-1}u))((I - \lambda W)^{-1}X\beta + (I - \lambda W)^{-1}u)'$$

$$= (I - \lambda W)^{-1}X\beta\beta'X'(I - \lambda W')^{-1} + (I - \lambda W)^{-1}u\beta'X'(I - \lambda W')^{-1}$$

$$+ (I - \lambda W)^{-1}X\beta u'(I - \lambda W')^{-1} + (I - \lambda W)^{-1}uu'(I - \lambda W')^{-1}$$

$$= (I - \lambda W)^{-1}X\beta\beta'X'(I - \lambda W')^{-1} + (I - \lambda W)^{-1}uu'(I - \lambda W')^{-1}$$

$$= (I - \lambda W)^{-1}X\beta\beta'X'(I - \lambda W')^{-1} + (I - \lambda W)^{-1}(I - \lambda W')^{-1}\sigma^{2}$$

then

$$V(y) = E(yy') - (E(y))^{2}$$
$$= [(I - \lambda W)'(I - \lambda W)]^{-1}\sigma^{2}$$
$$= \Omega \sigma^{2}$$

(7)

Maximum Likelihood Estimator

The associated likelihood function is then

$$\mathcal{L}\left(\sigma^{2},\lambda,y\right) = \left(\frac{1}{\sqrt{2\pi}}\right)^{n} |\sigma^{2}\Omega|^{-\frac{1}{2}} exp\left\{-\frac{1}{2\sigma^{2}}(y - (I - \lambda W)^{-1}X\beta)'\Omega^{-1}(y - (I - \lambda W)^{-1}X\beta)\right\}$$

the log likelihood

$$l\left(\sigma^2,\lambda,y\right) = constant - \frac{1}{2}ln|\sigma^2\Omega| - \frac{1}{2\sigma^2}(y - (I - \lambda W)^{-1}X\beta)'\Omega^{-1}(y - (I - \lambda W)^{-1}X\beta)$$

note that $|\sigma^2\Omega| = \sigma^{2n}|\Omega|$, and that

$$|\Omega| = |[(I - \lambda W)'(I - \lambda W)]^{-1}|$$

$$= |(I - \lambda W)^{-1}(I - \lambda W')^{-1}|$$

$$= |(I - \lambda W)^{-1}||(I - \lambda W')^{-1}|$$

$$= |(I - \lambda W)|^{-2}$$

Maximum Likelihood Estimator

so returning to the log likelihood we have that the log likelihood is

$$l(\sigma^{2}, \lambda, y) = constant - \frac{n}{2}ln(\sigma^{2}) + ln(|(I - \lambda W)|)$$
$$-\frac{1}{2\sigma^{2}} \left(y - (I - \lambda W)^{-1}X\beta\right)'(I - \lambda W)'(I - \lambda W) \left(y - (I - \lambda W)^{-1}X\beta\right)$$
(9)

then

$$l(\sigma^{2}, \lambda, y) = constant - \frac{n}{2}ln(\sigma^{2})$$

$$-\frac{1}{2\sigma^{2}}((I - \lambda W)y - X\beta)'((I - \lambda W)y - X\beta)$$

$$+ln(|(I - \lambda W)|)$$
(10)

Sarmiento-Barbieri (Uniandes)

Maximum Likelihood Estimator

- ► The determinant $|(I \lambda W)|$ is quite complicated because in contrast to the time series, where it is a triangular matrix, here it is a full matrix.
- Nowever, Ord (1975) showed that it can be expressed as a function of the eigenvalues $ω_i$

$$|(I - \lambda W)| = \prod_{i=1}^{n} (1 - \lambda \omega_i)$$

So the log likelihood is simplified to

$$l(\sigma^{2}, \lambda, y) = constant - \frac{n}{2}ln(\sigma^{2})$$
$$-\frac{1}{2\sigma^{2}}((I - \lambda W)y - X\beta)'((I - \lambda W) - X\beta)$$
$$+\sum ln(1 - \lambda \omega_{i})$$
(11)

Maximum Likelihood Estimator

Applying FOC, the ML estimates for β and σ^2 are:

$$\hat{\beta}_{MLE} = (X'X)^{-1}X'(I - \lambda W)y$$

$$\hat{\sigma}_{MLE}^2 = \frac{1}{n} (y - \lambda Xy - X \hat{\beta}_{MLE})' (y - \lambda Xy - X \hat{\beta}_{MLE})$$

ightharpoonup Conditional on λ these estimates are simply OLS applied to the spatially filtered dependent variable and explanatory variables X.

Maximum Likelihood Estimator

Substituting these in the log likelihood we have a concentrated log-likelihood as a nonlinear function of a single parameter λ

$$l(\lambda) = -\frac{n}{2}ln\left(\frac{1}{n}(e_0 - \lambda e_L)'(e_0 - \lambda e_L)\right) + \sum ln(1 - \lambda \omega_i)$$
 (12)

- \blacktriangleright where e_0 are the residuals in a regression of y on X and
- $ightharpoonup e_L$ of a regression of Wy on X.
- ► This expression can be maximized numerically to obtain the estimators for the unknown parameters λ .
- with λ^* , get $\hat{\beta}_{MLE}$ and $\hat{\sigma}_{MLE}^2$

Maximum Likelihood Estimator

The asymptotic variance follows as the inverse of the information matrix

$$AsyVar\left(\lambda,\beta,\sigma^{2}\right) = \begin{pmatrix} tr(W_{A})^{2} + tr(W_{A}'W_{A}) + \frac{(W_{A}X\beta)'(W_{A}X\beta)}{\sigma^{2}} & \frac{(X'W_{A}X\beta)'}{\sigma^{2}} & \frac{tr(W_{A})'}{\sigma^{2}} \\ \frac{(X'W_{A}X\beta)'}{\sigma^{2}} & \frac{(X'X)}{\sigma^{2}} & 0 \\ \frac{tr(W_{A})'}{\sigma^{2}} & 0 & \frac{n}{2\sigma^{4}} \end{pmatrix}^{-1}$$

$$(13)$$

- \blacktriangleright where $W_A = W(I \lambda W)^{-1}$.
- Note that
 - the covariance between β and σ^2 is zero, as in the standard regression model,
 - this is not the case for λ and σ^2 .

Two-Stage Least Squares estimators

- ▶ An alternative to MLE we can us 2SLS to eliminate endogeneity.
- Key is to identify proper instruments
 - ▶ Need to be uncorrelated with the error term
 - ► Correlated with *Wy*

Two-Stage Least Squares estimators

Consider the following

$$E(y) = (I - \lambda W)^{-1} X \beta$$

now, since $|\lambda| < 1$ we can use Neumann series property to expand the inverse matrix as

$$(I - \lambda W)^{-1} = I + \lambda W + \lambda^2 W^2 + \lambda^3 W^3 + \dots$$

hence

$$E(y) = (I + \lambda W + \lambda^2 W^2 + \lambda^3 W^3 + \dots) X\beta$$

$$= X\beta + \lambda WX\beta + \lambda^2 W^2 X\beta + \lambda^3 W^3 X\beta + \dots$$

so we can express E(y) as a function of X, WX, W^2X ,...

Two-Stage Least Squares estimators

We can use the first three elements of the expansion as instruments. Let's define *H* as the matrix with our instruments

$$H = [X, WX, W^2X]$$

Now,

$$y = \lambda Wy + X\beta + u$$

$$= M\theta + u$$

where
$$M = [Wy, X]$$
 and $\theta = [\lambda, \beta]$.

Two-Stage Least Squares estimators

- ► The first stage is: $M = H\gamma + \eta$
 - where $\hat{\gamma} = (H'H)^{-1}H'M$
 - ightharpoonup and $\hat{M} = H\hat{\gamma} = P_H M$
- ► The second stage is

$$y = \hat{M}\theta + u \tag{14}$$

and

$$\hat{\theta}_{2SLS} = (\hat{M}'\hat{M})^{-1}\hat{M}'y$$

$$= (M'P_HM)^{-1}M'P_Hy$$
(15)

 \blacktriangleright Consider the following model for the i-th observation

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_r x_{ir} + \dots + \beta_k x_{ik} \ i = 1, \dots, n$$

▶ Recall that in OLS we have

$$\beta_1 = \frac{\partial y_i}{\partial x_{i1}}$$

or generically

$$\beta_r = \frac{\partial y_i}{\partial x_{ir}} \quad \forall i = 1, \dots, n \& r = 1, \dots, k$$
$$\beta_r = \frac{\partial y_i}{\partial x_{ir}} \quad \forall j \neq i \& \forall r = 1, \dots, k$$

- ► Interpretation is straight forward as long as we take into account units
- ▶ In spatial models the interpretation is less immediate and require some clarification

Lets consider the case of a simple Spatial Lag model with a single regressor

$$y_i = \alpha + \beta x_i + \lambda \sum w_{ij} y_j + \epsilon_i \tag{16}$$

with $|\lambda|$ < 1, and

$$\beta \neq \frac{\partial y_i}{\partial x_i}$$

$$\frac{\partial y_i}{\partial x_i} = diag(I - \lambda W)^{-1}\beta$$

- ightharpoonup The impact depends also on the parameter λ
- ► The impact is different in each location

More generally consider

$$y = \lambda Wy + X\beta + u$$

= $(I - \lambda W)^{-1}X\beta + (I - \lambda W)^{-1}u$

Then

$$E(y) = (I - \lambda W)^{-1} X \beta \tag{17}$$

we define

$$S(W) = (I - \lambda W)^{-1} \beta \tag{18}$$

Therefore the impact of *each variable x* on *y* can be described through the partial derivatives $\frac{\partial E(y)}{\partial x}$ which can be arranged in the following matrix:

$$S(W) = \frac{\partial E(y)}{\partial x} = \begin{pmatrix} \frac{\partial E(y_1)}{\partial x_1} & \dots & \frac{\partial E(y_1)}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial E(y_i)}{\partial x_1} & \dots & \frac{\partial E(y_i)}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial E(y_n)}{\partial x_n} & \dots & \frac{\partial E(y_n)}{\partial x_n} \end{pmatrix}$$
(19)

On this basis, LeSage and Pace (2009) suggested the following impact measures that can be calculated for each independent variable X_i included in the model

Neerage Direct Impact: this measure refers to the impact of changes in the i-th observation of x_r , which we denote x_{ir} , on y_i . This is the average of all diagonal entries in S

$$ADI = \frac{tr(S_r(W))}{n}$$

$$= \frac{1}{n} \sum_{i=1}^{n} S_r(W)_{ii}$$
(20)

Neerage Total Impact To an observation: this measure is related to the impact produced on one single observation y_i from changing of the r-th independent variable across all other observations. For each observation this is calculated as the sum of the i-th row of matrix S

$$ATIT_{j} = \frac{\iota' S_{r}(W)}{n}$$

$$= \frac{1}{n} \sum_{i=1}^{n} S_{r}(W)_{ij}$$
(21)

Neerage Total Impact From an observation: this measure is related to the total impact on all other observations y_i from changing the r - th variable in j - th observation. For each observation this is calculated as the sum of the j - th column of matrix S

$$ATIF_{i} = \frac{1}{n} S_{r}(W)\iota$$

$$= \frac{\sum_{j=1}^{n} S_{r}(W)_{ij}}{n}$$
(22)

- ▶ A Global measure of the average impact obtained from the two previous measures.
- ► It is simply the average of all entries of matrix S

$$ATI = \frac{1}{n} \iota' S_r(W) \iota = \frac{1}{n} \sum_{i=1}^{n} ATIT_i = \frac{1}{n} \sum_{j=1}^{n} ATIF_i$$
 (23)

- ► The numerical values of the summary measures for the two forms of average total impacts are equal.
- ▶ The ATIF relates how changes in a single observation j influences all observations.
- ▶ In contrast, the ATIT considers how changes in all observations influence a single observation i.

► Average Indirect Impact obtained as the difference between ATI and ADI

$$AII = ATI - ADI (24)$$

ightharpoonup It is simply the average of all off-diagonal entries of matrix S_r

Interpretation of Parameters: Example

- ▶ We have data on 20 Italian regions on GDP and unemployment.
- ▶ We want to estimate the effect of GDP on Unemployment (Okun's Law)

	OLS	Spatial Lag Model
Intercept	10.971***	3.12275***
GDP	-3.326***	-1.13532***
λ	-	0.7476***
ADI	-	-1.542448
AII	-	-2.95571
ATI	-	-4.498159

Review & Next Steps
